OVERVIEW

This application note fully describes the working of a code hopping decoder implemented on a Microchip PIC16C56 microcontroller. This decoder uses the secure learn (seed-based) method of learning new transmitters. This application note describes the various Keeloq® code hopping encoders that can be used with the decoder, the decoder hardware, and the various software modules comprising the system. The software can be used to implement a stand alone decoder or integrate with full function security systems. The decoder supports the Microchip HCS200, HCS300, HCS301, HCS360, HCS361 and HCS410 Keeloq Code Hopping Encoders.

KEY FEATURES

- Stand alone decoder
- Compatible with Microchip HCS200, HCS300, HCS301, HCS360, HCS361 and HCS410 encoders
- Automatic bit rate detection
- Automatic encoder type detection
- Four function outputs
- Six learnable transmitters
- RC Oscillator

FIGURE 1: PIC16C56 DECODER

Notice:

This is a non-restricted version of Application Note AN652 which is available under the Keeloq License Agreement. The license agreement can be ordered from the Microchip Literature Center as DS40149.
INTRODUCTION TO KeeLoQ ENCODERS

All KeeLoQ encoders use the KeeLoQ code hopping technology to make each transmission by an encoder unique. The encoder transmissions have two parts. The first part changes each time the encoder is activated and is called the hopping code part and is encrypted. The second part is the unencrypted part of the transmission, principally containing the encoder's serial number identifying it to a decoder. Refer to DS91002, Introduction to KeeLoQ.

Hopping Code

The hopping code contains function information, a discrimination value, and a synchronization counter. This information is encrypted by an encryption algorithm before being transmitted. A 64-bit encryption key is used by the encryption algorithm. If one bit in the data that is encrypted changes, the result is that an average of half the bits in the output will change. As a result, the hopping code changes dramatically for each transmission and can not be predicted.

Function Information

The encoder transmits up to four bits of function information. Up to 15 different functions are available.

Discrimination Value

Stored in the encoder EEPROM, this information can be used to check integrity of decryption operation by a decoder. If known information is inserted into the transmitted string before encryption, the same information can be used at the decoder to check whether the information has been decrypted correctly. In the Microchip HCS encoders, up to 12 bits (including overflow bits) are available.

Synchronization Counters

The transmitted word contains a 16-bit synchronization counter. The synchronization information is used at the decoder to determine whether a transmission is valid or is a repetition of a previous transmission. Previous codes are rejected to safeguard against code grabbers.

Unencrypted Code

Serial Number

The encoder's serial number is transmitted every time the button is pressed. The serial number is transmitted unencrypted as part of the transmission and serves to identify the encoder to the decoder.

Other Status and Function Information

The HCS200, HCS300, and HCS301 encoders include provision for four bits of function information and two status bits in the fixed code portion of its transmission. The two status bits indicate whether a repeated transmission is being sent, and whether the battery voltage is low. The HCS200 does not send repeated transmission information, and the bit is permanently set to ‘0’.

The HCS360/361 encoders transmit two bits that are used as a Cyclic Redundancy check. These bits can be used to check the integrity of the reception. Additionally, the HCS360 and HCS361 encoders can extend the length of the serial number from 28 bits to 32 bits, replacing the unencrypted function code.

Seed Transmissions

The Microchip HCSXXX encoders all have the ability to transmit a fixed seed. The seed value is programmed into the encoder when the encoder is first initialized along with the counters, key, serial number, and other information. The seed length differs from encoder to decoder with the HCS200, HCS300, and HCS301 having a 32-bit seed. The HCS360 and HCS361 encoders have a 48-bit seed. The HCS410 has a 60-bit seed. Table 1 summarizes seed transmissions in the Microchip HCSXXX encoders.

**PWM Format**

In general, all Keeloq encoders share a common transmission format:

- **A preamble** to improve biasing of decision thresholds in super-regenerative receivers. The preamble consists of alternate on and off periods, each lasting as long as a single elemental period.

- **A calibration** header consisting of a low period of 10 elemental periods. Calibration actions should be performed on the low period of the header to ensure correct operation with header chopping.

- **A string** of pulse-width modulated bits, each consisting of three elements. The first element is high, the second contains the data transmitted and is either high or low, the third element is always low.

- **A guard** period is usually left between the transmissions. During this period nothing is transmitted by the encoder.

Figure 3 shows the sampling points when sampling the data bits. The first and last elements are used exclusively to verify the integrity of the received symbol. The first element (sample point A) is always high, the second (sample point B) is the complement of the data bit being sent, and the final element (sample point C) is always low. Because the period between the low portion of a bit (sample point C) and the rising edge of the following bit (sample point X) can vary, the rising edge of the first element (sample point X) is used to resynchronize the receiving routine to each incoming bit.

If random noise is being received, the probability of a set of three samples producing a valid combination is only $2^{-2} = 1/4$. For a string of 66 bits, the corresponding figure is $2^{-134}$.

Integrity checking on incoming signals is important. Code hopping signals require significant processing, as well as EEPROM access, to decrypt. Unnecessary processing can be avoided by not attempting to decrypt incoming codes that have bit errors.

DECODER IMPLEMENTATION

The Microchip decoder's primary hardware components are a PIC16C56 RISC microcontroller and a 93LC46B EEPROM as shown in the decoder schematic in Figure 10. However, this solution can be implemented in any PICmicro® microcontroller with at least 1K words of program memory. The operating frequency of the controller is 4 MHz. The microcontroller is used to capture transmissions from the various encoders, decrypt transmissions captured, and check the validity of the transmission based on the information in the decrypted transmission and information stored in the EEPROM. If a transmission from a valid encoder is received, the decoder activates the outputs dictated by the transmission.

Encoder information, such as serial number, synchronization information, and decryption key is stored externally in an EEPROM. The EEPROM used is a Microchip 93LC46B Microwire® Serial EEPROM. The information stored in the EEPROM is encrypted to protect the contents. The EEPROM encryption is less secure than the KeeLoq code hopping algorithm.

As can be seen from the section on encoder transmissions, there are differences in the transmission formats of the different encoders that can be used with the decoder. The following section summarizes how the differences in transmitted data are dealt with by the decoder.

As the serial number information follows after the code hopping portion of the transmission, any number of serial number bits can be received and processed. In the Microchip decoder described, the complete serial number (28 bits) is stored.

The serial number is used to identify the memory block used to store the 64-bit decryption key for a particular encoder because of the relationship between serial number, seed, and the decryption key. In other words, the serial number is stored with the key. When a transmission is received, the decoder finds the correct memory block by checking all blocks until a matching serial number is found. The key is then retrieved from that particular memory block. A serial number of 000000016 is considered invalid and is ignored by the decoder.

After matching the received and stored serial number, validation of a received transmission consists of two steps. The first includes checking the integrity of the decryption operation. Here the decoder compares the 12-bit discrimination value received with the stored discrimination value. The discrimination value stored with the HCS300/301/360/361/410 includes overflow bits and user bits.

The second portion of validation involves checking synchronization information for that particular encoder. The synchronization counter transmitted by all encoders is 16 bits long. Two copies of the full synchronization counter are stored for all valid encoders. The storing of two copies of the synchronization information protects the decoder from losing synchronization with an encoder if one of the counters is corrupted.

TABLE 9: MICROCHIP DECODER FUNCTIONAL INPUTS AND OUTPUTS
**PROGRAM FLOW**

The software for the Microchip decoder has been written for the PIC16C56 microcontroller. The compiler used is MPASM version 01.30.01. The operating frequency of the PIC16C56 is 4 MHz. The clock speed should be kept as close as possible to 4 MHz as the reception routine (RECEIVE) is dependent on the 4 MHz clock for correct functioning. Other decoder functions that rely on a 4 MHz clock speed are the hold times of the various outputs and time-outs. The main program flow is described here. Detailed descriptions of individual functions can be found further in the application note.

As can be seen from Figure 5, the decoder reads the learn indicator, which stores the next position to be overwritten when the decoder enters a learn sequence and decoder status flags, from the external EEPROM on power-up. The status flags are checked to see if a learn routine was interrupted when the microcontroller was reset. If so, it is assumed the learn cycle was not successfully completed, and the encoder at the learn indicator is subsequently deleted (WIPE_TX).

The encoder then enters the main loop where it spends most of its time. The main loop checks to see if the learn button is being activated (TST_LEARN). If so, the decoder enters the learn mode described in the "Learn" section in AN652.

If learn has not been initiated, the microcontroller then checks for transmissions from encoders (RECEIVE). If a transmission from an encoder has successfully been received, the microcontroller validates the transmission received as described in the "Transmission Validation" in AN652. If the transmission received is a valid transmission from an encoder learned into the system, the system sets the appropriate outputs (M_BUT).
FUNCTIONAL MODULES

Reception

The reception routine (RECEIVE) is based on a reliable algorithm which has successfully been used in previous implementations of KEELOQ decoders. Automatic bit-rate detection is used to compensate for variations in bit rate of different encoders of a specific type, as well as the differences in bit rate between different encoders (HCS200, HCS300, and HCS360). The reception routine is able to receive 64-bit transmissions. This is easily extended to receive more bits. The reception routine is able to determine the number of bits in the transmission.

The reception algorithm performs a number of functions when an output is detected from the receiver. Figure 6 gives all the major sampling points in the reception algorithm.

The reception algorithm calibrates on the low period of the header to determine the actual elemental period for the transmission being received. The required elemental period is 10% of the low header period. In Figure 6 the header calibration sample points are marked 1 through 3. The calibration flow chart (Figure 7) shows at what points in the program samples 1, 2, and 3 are taken.

Elemental periods outside the capture range of the algorithm (either too long or too short) are rejected, since they are due either to noise or to reception of an incomplete signal.

Using the determined elemental period, three samples after the first rising edge (Sample 3) following the header are taken. The first sample is taken half an elemental period after the rising edge (Sample 4); the second, one elemental period later (Sample 5), and the third, another one elemental period later (Sample 6). The first sample must be high, the second could be either high or low, and the third sample must be low. If either the first or the third sample is not as expected, the attempt at capturing a transmission is abandoned. In Figure 6, the data sample points are points 4 through 6. The flow chart describing data reception (Figure 8) shows where in the code the samples are taken.

If all 66 bits have been captured, each with the correct first and third elements, the transmission can be assumed to be correct, and decryption can commence. The receiving routine should be called often enough to ensure that the high portion in the header is not missed (Sample 1, Figure 6).

In systems where the reception routine is called to check if there is activity on the receiver input, the routine should poll the input for a valid transmission for at least the time taken to complete one transmission if activity is detected on the input line. This makes provision for the reception routine being called while a transmission is in progress. Having missed the first header, the first transmission will be invalid and be discarded. The decoder should continue sampling the input through the guard time in order to catch the next header and transmission (i.e., for a decoder designed to capture HCS300 transmissions the time spent polling for a valid transmission should be at least 100 ms if activity is detected in the input line).

Reception Algorithm Flow Chart

The first flow chart (Figure 7) describes the calibration routine which is used to determine the actual transmission rate of the encoder so that the decoder can compensate for deviations from nominal timing. There are four different exit points, each of which should branch to a point in the program where housekeeping and input monitoring can be resumed. There is only one exit point for a valid calibration operation (RCV7). At this point, it is assumed that a valid header has been received and that a string of data bits will follow.

The second flow chart (Figure 8) handles the reception of bits once the calibration routine has been successfully completed. The data bits are all sampled three times each to ensure that a noise free transmission has been received. The reception routine uses the calibrated elemental period, determined in the calibration routine, to ensure that the samples are correctly spaced. The routine resynchronizes itself on the rising flank of each bit. Only 60 bits of the data received are used by the Microchip decoder described, the decoder ignores the unencrypted function code and the status bits.

If the control samples in a given bit are sampled correctly (i.e., the first element is high and the last element is low), the routine checks whether more than 56 bits have been received correctly. If not, the routine returns to the calling procedure.

SOURCE CODE LISTING

A diskette is supplied containing source code for the Microchip decoder in the file MSLRN**.ASM. The code has been compiled using MPASM v01.30.01. Certain functions are dependent on the oscillator speed for correct functioning. Examples of time dependent functions include RECEIVE and TST_RTCC. The PIC16C56 Microcontroller should run at 4 MHz.

NOTE: Two buttons are required.
FIGURE 12: HCS360/361 SINGLE BUTTON TRANSMITTER DESIGN
Note the following details of the code protection feature on PICmicro® MCUs.

- The PICmicro family meets the specifications contained in the Microchip Data Sheet.
- Microchip believes that its family of PICmicro microcontrollers is one of the most secure products of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the PICmicro microcontroller in a manner outside the operating specifications contained in the data sheet. The person doing so may be engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable”.
- Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our product.

If you have any further questions about this matter, please contact the local sales office nearest to you.
